

SWEET CORN HYBRID DISEASE NURSERY – 2006

JERALD PATAKY, MARTY WILLIAMS*, BRYAN WARSAW, MIKE MEYER, AND JIM MOODY*, DEPARTMENT OF CROP SCIENCES, UNIVERSITY OF ILLINOIS, URBANA, IL 61801 AND USDA-ARS*, URBANA, IL 61801

Common rust, northern leaf blight (NLB), Stewart's wilt, maize dwarf mosaic (MDM) southern leaf blight (SLB) and southern rust can reduce yields of susceptible and moderately susceptible sweet corn hybrids. These diseases can be managed more efficiently if reactions of hybrids are known.

Resistance and susceptibility are the two extremes of a continuum of host reactions to diseases. Resistance is a measure of the ability of the host to reduce the growth, reproduction, and/or disease-producing abilities of the pathogen, thus resulting in less severe symptoms of disease. Major genes for resistance, such as *Rp1-D*, *Rpp9*, *Ht1*, or *Mdm1*, can prevent or substantially limit disease development if specific virulence (i.e., races) is not prevalent in pathogen populations. Hybrids with major gene resistance usually have clearly distinguishable phenotypes. Major gene resistance may be ineffective if specific virulence occurs, such as the *Rp1-D*-virulent race of the common rust fungus and race 1 of the northern leaf blight fungus.

In the absence of effective major gene resistance, disease reactions often range from partially resistant to susceptible. Hybrids can be grouped into broad classes such as: resistant (R), moderately resistant (MR), moderate (M), moderately susceptible (MS), and susceptible (S) based on severity of disease symptoms. This procedure produces statistically "overlapping" groups without clear-cut differences between classes (e.g., the hybrid with least severe symptoms in the MR class does not differ significantly from the hybrid with the most severe symptoms in the R class).

Nevertheless, a consistent response over several trials produces a reasonable estimate of the disease reaction of a hybrid relative to the response of other hybrids. These reactions can be used to assess the potential for diseases to become severe and affect yield.

Sweet corn hybrids can also be damaged by certain postemergence herbicides. Reactions of hybrids to herbicides can be classified in a manner similar to disease reactions. This information can be used to identify sweet corn hybrids with the greatest risk of being damaged and to develop lists of hybrids on which specific herbicides should not be used.

This report summarizes the reactions of 379 sweet corn hybrids to Stewart's wilt, common rust, NLB, MDM, SLB, and southern rust based on their performance in the University of Illinois sweet corn disease nursery in 2006. The reactions of these hybrids to post-emergence applications of Callisto and Accent herbicides also are reported.

MATERIALS AND METHODS

Hybrids: Three hundred and seventy-nine hybrids were evaluated in 2006. This included 217 *sh2* hybrids, 81 *se* hybrids and 81 *su* hybrids. Hybrids with multiple endosperm mutations were placed in the most appropriate of these three categories. Standard hybrids with relatively consistent reactions to common rust, Stewart's wilt, NLB, MDM, and SLB (Table 1) were included to compare the results from the 2006 nursery to those from previous nurseries.

Table 1. Reactions of sweet corn hybrids included as standards in the 2006 disease nursery

Hybrid	Stewart's wilt			Rust G-virulent			NLB (races 0 & 1)			MDM				SLB

Prior - reaction in previous years (1984-2004).

06 - reaction in 2006: 1 - resistant, 3 - moderately resistant, 5 - moderate, 7 - moderately susceptible, 9 - susceptible.

Rating - 2006 mean rating: 1 to 9 for Stewart's wilt and SLB; 0 to 100% severity of NLB and common rust, 0 to 100% incidence of MDM.

Experimental design and procedures: Each disease was a separate trial with two replicates of hybrids arranged in randomized complete blocks. Each trial was split into two main blocks: *sh2* hybrids and *su* or *se* hybrids. Each experimental unit was a 12-ft. row with about 15 plants per row. All trials were planted May 23 on the University of Illinois South Farms. Trials in which G-virulent and avirulent common rust were evaluated were in isolated fields. Six other trials were planted in one field, including: Stewart's wilt, NLB, D-virulent common rust, MDM, and evaluations of two herbicides, Callisto and Accent. The herbicide trials were subsequently used to assess reactions of hybrids to SLB and southern rust, respectively.

Inoculation and disease assessment: Trials were inoculated with: *Erwinia stewartii* (Stewart's wilt), *Exserohilum turcicum* (NLB) races 0 and 1, maize dwarf mosaic (MDM) virus strains A and B (SCMV), and three isolates of *Puccinia sorghi*: Rp1-D/Rp-G-avirulent (avirulent), Rp1-D-virulent (D-rust), and Rp-G-virulent (G-rust). Following assessment of plant injury to herbicides, plants in the herbicide trials were inoculated with either *Bipolaris maydis* (SLB) or *Puccinia polysora* (southern rust). Plants were inoculated with *E. stewartii* on June 14 and 22 by wounding leaves in the whorl and introducing bacteria into wounds. A mixture of conidia of races 0 and 1 of *E. turcicum* were sprayed into plant whorls June 13, 16, 21, 28 and July 5. Plants were inoculated with MDMV-A and B on June 12 and 15 by wounding leaves in the whorl and introducing viruses into wounds. In the trials inoculated with each of the races of rust, urediniospores of *P. sorghi* were sprayed into plant whorls: G-virulent: June 14, 19, 21, and 27; D-virulent: June 12, 16, 20, 22, 26, and 30; and avirulent: June 15, 19, and 22. Plants in the Callisto trial were inoculated with *B. maydis* by spraying conidia into whorls on June 23, 27, 29 and July 6. Plants in the Accent trial were inoculated with *P. polysora* by spraying urediniospores in whorls on June 27, July 6 and 10.

The total number of plants and the number of plants infected with MDM were counted June 26-29 in each row in the MDM trial. Incidence (%) of MDM-infected plants was calculated from totals of both replicates of a hybrid. Incidence of virus-infected plants also was measured August 4-8 in the same plots. For other diseases, symptom severity was rated. Each plot (row) was given a separate rating by two people. Stewart's wilt was

rated July 7-8 using a scale from 1 (symptoms within 2 cm of inoculation wounds) to 9 (severe systemic infection or dead plants). Percent leaf area infected with common rust was rated August 1-2 in the G-virulent rust trial and August 2-3 in the D-virulent trial. In the avirulent trial, the presence or absence of uredinia was recorded July 10 in order to determine if a hybrid carried an Rp gene for resistance. Leaf area infected with NLB was rated from 0 to 100% August 7-8. Hybrids with chlorotic lesions typical of Ht-resistance also were noted. Symptoms of SLB and southern rust were rated on a 1 to 9 scale (very mild to severe) August 3-4 and August 10-11, respectively.

Herbicide application and assessment: Post-emergence herbicides were applied June 15 when plants ranged from the 4- to 5-leaf stages and from about 8 to 12 inches. Accent was applied at 1.34 oz./A with a 1%v/v crop oil concentrate (COC) and 2 qt/A 28% UAN. Callisto was applied at 6.0 oz./A with 1% v/v (COC) and 2.5% v/v 28% UAN. The entire field had been treated pre-emergence with metachlor + atrazine.

Corn injury was rated visually June 21, 6 days after application. Each row was given two ratings and classified from 1 to 9, where 1 = no injury apparent, 5 = moderate injury, 9 = severe injury.

Data analysis: Disease ratings were analyzed by ANOVA. Hybrid reactions to diseases and herbicides were classified from 1 (highly resistant) to 9 (highly susceptible) according to standard deviations from the mean (z-scores), Bayesian least significant difference (BLSD) separations ($k=100$), ranks of standard hybrids, and/or the FASTCLUS procedure of SAS using various groupings of 6 to 12 clusters.

RESULTS AND DISCUSSION

Symptoms ranged from very little disease to severely infected plants (Table 3). Reactions of standard hybrids to Stewart's wilt, common rust, NLB, MDM, and SLB were generally within expected ranges (Table 1). The criteria for classifying hybrid reactions are listed in Table 2. Table 3 includes reactions and actual ratings of the 379 hybrids **based solely on the 2006 trial**. This is the only data we have for some of these hybrids. For hybrids that have been evaluated in previous years, an assessment of disease reactions based on multiple trials is presented in another report.

Table 2. Criteria for classifying hybrid reactions to diseases in the 2006 nursery

Rp	Classification of reaction								
	Resistant 0	Moderately resistant 1	Moderately resistant 2	Moderate 3	Moderate 4	Moderately susceptible 5	Moderately susceptible 6	Susceptible 7	Susceptible 8
Common rust G (%) ≤2	< 10	< 13	< 16	< 20	< 25	< 30	< 35	≥ 35	
Common rust D (%) <5	< 10	< 14	< 20	< 25	< 28	< 33	< 36	≥ 36	
NLB races 0&1 (%)	≤ 10	≤ 15	≤ 20	≤ 24	< 27	< 32	< 36	≤ 40	
Stewart's wilt (1-9)	≤ 2	≤ 2.5	≤ 3	< 3.5	< 4	< 4.5	< 5	< 6	≥ 6
MDM-early (%)	0	< 10	< 15	< 20	< 30	≤ 40	≤ 60	< 80	≥ 80
MDM-late (%)	< 5	≤ 10	< 25	≤ 40	≤ 60	< 70	< 80	< 90	≥ 90
SLB (1-9)	≤ 1.5	≤ 2	< 2.5	< 3	< 3.5	< 4	< 5	< 6	≥ 6
Southern rust (1-9)	0	≤ 2	< 4	≤ 4.5	≤ 5.5	< 6.5	< 7	< 7.5	< 8
Accent (0-2)	0				< 0.5	< 1	< 1	< 2	2
Callisto (0-2)	0				< 0.5	< 0.6	< 1	< 1.5	< 2

See text for description of disease and herbicide assessments.

Stewart's wilt. Stewart's wilt ratings ranged from 1.3 to 7.2 with a mean of 3.8. Eighty-one hybrids that were rated 4.5 or higher (i.e., frequent systemic infection) were classified as moderately susceptible to susceptible (7 to 9). Hybrids that were rated from 3 to 4.5 (i.e., occasional systemic infection) were classified as moderate (4 to 6). Symptoms of Stewart's wilt were minor on 23 hybrids classified as resistant or R/MR (1 or 2) and on 56 hybrids with ratings from 2.5 to 3 that were classified as moderately resistant (3). Seven hybrids rated 2 or below were not different from Exp 6, the hybrid with the least severe symptoms. These included: Bonus, CSUWP1-7, CSUYP2-30, 179A, Mirai 334BC, Overland, and XTH 2179. Yield is affected minimally if Stewart's wilt is non-systemic, i.e., ratings <3. Of the 79 hybrids with R to MR reactions to Stewart's wilt, 8 were se, 49 were sh2, and 22 were su.

Northern leaf blight. Severity of NLB (% leaf area symptomatic) ranged from 6% to 48% and averaged 25% in the 2006 trial. In comparison, severity ranged from 8% to 86% and averaged 38% in 2005. NLB severity was 32% or higher on 68 hybrids with moderately susceptible to susceptible reactions (7 to 9). Two-hundred-and-six hybrids with 20% to 31% severity were classified between MR and MS (4 to 6).

Severity was 10% or less on 14 hybrids classified as resistant (1), including: 1283, 182A, 382A, B-235, B-375, Exp 6, GG Code 188, GSS 3186, Holiday, Merkur, Obsession, Overland, Ranger, and Sentinel. Forty-six hybrids with 10% to 15% leaf area infected were classified as R/MR (2). Forty-four hybrids that were classified as moderately resistant (3) had 15% to 20% leaf area

infected. Effects of NLB on yield are minimal when NLB severity is below 20%. Of the 104 hybrids with R to MR reactions to NLB, 12 were se, 73 were sh2, and 19 were su.

Thirteen of the 14 hybrids classified as R had chlorotic lesions indicative of an *Ht* gene that conveyed resistance to *E. turcicum* race 0. NLB severity averaged 19% and ranged from 6% to 37% on 145 hybrids with *Ht*-gene reactions. Severity averaged 28% with a range from 11% to 48% for 234 hybrids without *Ht*-gene reactions.

Maize dwarf mosaic. Incidence of MDM-infected plants 2 weeks after inoculation (about 6- to 7-leaf stage) ranged from 0 to 100% and averaged 57%. When MDM was rated 6 weeks later (about 1 wk past fresh corn harvest), average incidence of viral-infected plants increased to 85%. At the later rating, plants may have been infected by naturally-occurring MDM or by other maize viruses that were not easily distinguished from MDM.

Eleven hybrids classified as resistant (1) were completely asymptomatic at the early rating and had less than one infected plant at the later rating; including: 0873-5414, 0875-5781, 0875-6690, CSABF5-196, CSUYP2-28, Evita, EX 0873-5807, EX 0875-5821, Exp 12, Green Giant Code 186, and UY 0712 OJ. Twenty-three additional hybrids were entirely asymptomatic at the early rating but had 3% to 59% symptomatic plants at the later rating. These hybrids were classified as R/MR to MR (2-3). Thirteen other hybrids classified as MR (3) had 10% or less symptomatic plants at the early rating and 11% to 59% symptomatic plants at the later rating. Of the 47 hybrids classified R to MR, 4 were se hybrids, 15 were sh2 hybrids, and 28 were su hybrids.

Incidence of MDM ranged from 0 to 49% at the early rating and from 16% to 100% at the late rating for 30 hybrids classified as having moderate reactions to MDM (i.e., 4 to 6). Incidence of viral-infected plants at the late rating was greater than 75% for 296 of the 301 hybrids classified as moderately susceptible to susceptible (7 to 9). At the early rating, incidence was greater than 50% for 263 of these 301 hybrids. At the late rating, incidence of plants with symptoms of viral infection was 100% for 275 hybrids.

Southern leaf blight. SLB ratings (1 to 9 scale) ranged from 1 to 7.3 and averaged 2.6. Ratings were 4 or above for 50 hybrids classified as moderately susceptible to susceptible to SLB (reactions of 7 to 9). One-hundred-and-thirty-six hybrids with ratings from 2.5 to 4 were classified between MR and MS (4 to 6). The majority of hybrids (192) were classified as R to MR with ratings lower than 2.5. Fifty-five hybrids with ratings of 1.5 and below included 6 *se* hybrids, 36 *sh2* hybrids, and 13 *su* hybrids.

Southern rust. Southern rust ratings (1 to 9 scale) ranged from 0 to 9 and averaged 6.4. Ratings were above 7 for 133 hybrids classified as moderately susceptible to susceptible (reactions of 7 to 9). Two-hundred-and-sixteen hybrids with ratings from 4.5 to 7 were classified between MR and MS (4 to 6). Eight hybrids with ratings from 4 to 4.5 were classified as moderately resistant. Ten hybrids with ratings below 4 were classified as R/M or R, including: Charisma, Exp 11, HMX 1368 WS, Lancelot, Merlin, Native Gem, Precious Gem, Spring Treat, Sugar Pearl, and Tuxedo. Uredinia of southern rust were not observed on two hybrids, Calvary and Sure Gold. These hybrids likely carry the *Rpp9* gene for resistance. Of the 18 hybrids classified from R to MR for southern rust (excluding the two hybrids with *Rpp*-reactions), 13 were *se* hybrids, 2 were *sh2* hybrids, and 3 were *su* hybrids.

Common rust. Excluding hybrids with Rp-resistant reactions, severity of common rust ranged from 2% to 44% and averaged 18% in the trial inoculated with G-virulent *P. sorghi* and from 9% to 41% with an average of 24% in the trial inoculated with D-virulent *P. sorghi*.

In the trial inoculated with avirulent *P. sorghi*, uredinia were not observed on 191 hybrids. Of these 191 hybrids, 130 were Rp-resistant only in the G-virulent trial, 29 were Rp-resistant only in the D-virulent trial, and 32 were Rp-resistant in both the G-virulent and D-virulent trials. Of the 32 hybrids resistant to G-virulent and D-virulent rust, 2 were *se* hybrids, 15 were *sh2* hybrids, and 15 were *su* hybrids.

Among the 130 hybrids that were Rp-resistant in the G-virulent trial, 19 had 28% or more leaf area infection (severity) in the D-virulent trial and were classified as MS to S. Of the 29 hybrids that were Rp-resistant in the D-virulent trial, five had rust severity of 25% or more in the G-virulent trial and were classified as MS to S.

Among the 188 hybrids that did not have Rp-resistance, the correlation between rust severity in the G-virulent and D-virulent trials was 0.72. Thirteen hybrids were moderately resistant with rust severity of 12% or less (G-virulent trial) and less than 20% (D-virulent trial). These included: Captivate, CSAB5-197, EX 0870 8188, GG Code 6, GG Code, 27, GG Code 61, GG Code 192, Lancelot, Miracle, Mirai 308BC, Synergy, Turbo, and XTH 1179. Among the 188 hybrids that did not have Rp-resistance, 58 hybrids were classified as MS to S in either the G-virulent or D-virulent trial.

Reactions to herbicides. Most hybrids were not affected by post-emergence applications of Callisto or Accent (Table 3). Ninety-eight hybrids displayed some symptoms of injury from Callisto. Callisto injury was severe (classified 7 to 9) on 14 hybrids: 0873 6987, 178A, Argent, B-146, CSHWF5-203, DMC 20-38, FL 3656, HMX 6386S, Merit, Supersweet Jubilee Plus, XP 0870 5770, XTH 1774, XTH 2477, and XTH 3175. Eight hybrids were injured severely by Accent: DMC 20-38, EX 0845 6347, FL 3656, HMX 6386S, Merit, XP 0870 5770, XTH 1774, and XTH 3175. Three were moderately injured: B-146, WH 0809, and WSS 1262. Previously, we observed an association among hybrid sensitive to Accent and Callisto. Hybrids sensitive to both herbicides may be homozygous for a gene that inhibits metabolism of these herbicides. Hybrids with moderate injury from Callisto and no symptoms of injury from Accent may be heterozygous for this gene.

Rxn - classification of hybrid disease reactions: 1 - resistant, 3 - moderately resistant, 5 - moderate, 7 - moderately susceptible, 9 - susceptible

Rate - disease rating: 1 to 9 scale (Stewart's wilt, SLB, southern rust); 0 to 100% leaf area infected (NLB, G-virulent rust, D-virulent rust); 0 to 100% incidence of infected plants (MDM)

Seed source: AC - Abbott & Cobb, Bas - Basso, Cen - Centest, Cr - Crookham, DM - Del Monte, GG - Green Giant, HM - Harris Moran, IFS - Illinois Foundation Seeds, MM - Mesa Maize, PV - Pop Vriend, Rog - Rogers (Syngenta), Rsp - Rispens, Sem - Seminis, SnR - Snowy River
